Abstract

A congenital coronary cameral fistula (CCCF) is characterized by left ventricular dysfunction, electrocardiographic changes due to a reduced left coronary blood flow and impaired physical activity. CCCF's with a giant aneurysm are very rarely seen. The presence of a giant aneurysm imposes even greater health risks. We report a case of a CCCF from the left coronary artery to the right ventricle with a large distal aneurysm in a 20-year-old woman that we closed percutaneously with coils for the closure of ventricular septal defects (VSD) and persistent ductus arteriosus (PDA).
